**Part I.**

# **Category Theory in Context**

# 1. Categories, Functors, Natural Transformations

## 1.1. Abstract and concrete categories

### 1.1.i

*Proof.* Observe that  $ghf : y \rightarrow x$ . Also  $ghf = (gf)h = h$  and  $ghf = g(fh) = g$ , thus  $g = h$ . This means that  $f$  has an inverse morphism  $g$  such that  $fg = 1_x$  and  $gf = 1_y$ , so  $f$  must be an isomorphism.  $\square$

### 1.1.ii

*Proof.* First we show that the collection of isomorphisms in  $\mathcal{C}$  with the objects of  $\mathcal{C}$  forms a category. The identity morphism exists in the new category since it is its own inverse and therefore an isomorphism. Associativity is inherited from morphisms on  $\mathcal{C}$ . To prove composability, say  $f : x \rightarrow y$  and  $g : y \rightarrow z$  are isomorphisms, i.e., there exist  $f_*$  and  $g_*$  such that  $ff_* = 1_y$ ,  $f_*f = 1_x$  and  $gg_* = 1_z$ ,  $g_*g = 1_y$ . Clearly  $gf$  is a morphism since so are  $f$  and  $g$ . We claim that  $f_*g_*$  is its inverse morphism, which is trivial to verify. Hence  $gf$  is an isomorphism. It is clear that the resultant category is a groupoid so let us prove its maximality. Suppose to the contrary that there is a larger groupoid  $\mathcal{C}'$  containing it. Since they have the same objects,  $\mathcal{C}'$  must contain an isomorphism not in  $\mathcal{C}$ . This is a contradiction because  $\mathcal{C}$  contains all the isomorphisms between its objects.  $\square$

### 1.1.iii

*Proof.* Associativity follows in either case because the maps in  $\mathcal{C}$  are associative.

- (i) First note that there is an identity morphism for every  $f : c \rightarrow x$  because we can take  $g = f$ . To show composability, let  $h_1 : a \rightarrow b$  be from  $f : c \rightarrow a$  to  $g : c \rightarrow b$  and  $h_2 : b \rightarrow d$  be from  $g : c \rightarrow b$  to  $h : c \rightarrow d$ . Note that  $g = h_1f$  and  $h = h_2g$  implies  $h = h_2(h_1f) = (h_2h_1)f$  and so the diagram with  $h_2h_1$  also commutes.
- (ii) Identity morphism for  $f$  is found by taking  $g = f$ . To show composability, proceed as before  $f = gh_1 = (hh_2)h_1 = h(h_2h_1)$ .

$\square$

## 1.2. Duality

**Part II.**

**Tom Leinster**
